Gradual onset of
Glauber-Gribov multiple
interactions

Preequilibrium
Coalescence
Hadron-nucleon interaction models

Elastic, charge exchange and strangeness exchange reactions:
- Available phase-shift analysis and/or fits of experimental differential data
- At high energies, standard eikonal approximations are used

Particle production interactions: two kinds of models
- Those based on "resonance" production and decays, cover the energy range up to 3-5 GeV
- Those based on quark/parton string models, which provide reliable results up to several tens of TeV

p-p and p-n cross section
FLUKA and data

Elastic, charge exchange and strangeness exchange reactions:
- Available phase-shift analysis and/or fits of experimental differential data
- At high energies, standard eikonal approximations are used
Nonelastic hN interactions at intermediate energies

- $N_1 + N_2 \rightarrow N_1' + N_2' + \pi$ threshold at 290 MeV, important above 700 MeV,
- $\pi + N \rightarrow \pi' + \pi'' + N'$ opens at 170 MeV.

Anti-nucleon -nucleon open at rest!

Dominance of the $\Delta$ resonance and of the $N^*$ resonances
- isobar model
- all reactions proceed through an intermediate state containing at least one resonance.

Resonance energies, widths, cross sections, branching ratios from data and conservation laws, whenever possible. Inferred from inclusive cross sections when needed

$N_1 + N_2 \rightarrow N_1' + \Delta(1232) \rightarrow N_1' + N_2' + \pi$
$\pi + N \rightarrow \Delta(1600) \rightarrow \pi' + \Delta(1232) \rightarrow \pi' + \pi'' + N'$
$N_1, N_2 \rightarrow \Delta_1(1232) + \Delta_2(1232) \rightarrow N_1' + \pi_1 + N_2' + \pi_2$
Inelastic hN at high energies: (DPM, QGSM, …)

- Problem: “soft” interactions $\rightarrow$ QCD perturbation theory cannot be applied.
- Interacting strings (quarks held together by the gluon-gluon interaction into the form of a string)
- Interactions treated in the Reggeon-Pomeron framework
- each of the two hadrons splits into 2 colored partons $\rightarrow$ combination into 2 colourless chains $\rightarrow$ 2 back-to-back jets
- each jet is then hadronized into physical hadrons
Leading two-chain diagram in DPM for p-p scattering. The color (red, blue, and green) and quark combination shown in the figure is just one of the allowed possibilities.

Leading two-chain diagram in DPM for π⁺-p scattering. The color (red, blue, and green) and quark combination shown in the figure is just one of the allowed possibilities.
**DPM and hadronization**

**from DPM:**
- Number of chains
- Chain composition
- Chain energies and momenta
- Diffractive events

**Chain hadronization**
- Assumes chain universality
- Fragmentation functions from hard processes and $e^+e^-$ scattering
- Transverse momentum from uncertainty considerations
- Mass effects at low energies

*Almost No Freedom*

The same functions and (few) parameters for all reactions and energies
Inelastic hN interactions: examples

\[ \pi^+ + p \rightarrow \pi^+ + X \ (6 \ & 22 \text{ GeV/c}) \]

\[ \pi^+ + p \rightarrow \text{Ch}^+/\text{Ch}^- + X \ (250 \text{ GeV/c}) \]

\[ p + p \rightarrow p + X, \ 6 \text{ and } 22 \text{ GeV/c} \]

\[ p + p \rightarrow C^+/C^- + X, \ 250 \text{ GeV/c} \]

M.E. Law et al, LBL80 (1972)
Nuclear interactions in PEANUT:

1. **Target nucleus description (density, Fermi motion, etc)**

2. **Glauber-Gribov cascade with formation zone**

3. **Generalized IntraNuclear cascade**

4. **Preequilibrium stage with current exciton configuration and excitation energy**
   - (all non-nucleons emitted/decayed + all nucleons below 30-100 MeV)

5. **Evaporation/Fragmentation/Fission model**

6. **γ deexcitation**

- **Time Scale (s)**:
  - $10^{-23}$
  - $10^{-22}$
  - $10^{-20}$
  - $10^{-16}$
Nucleon Fermi Motion

- Fermi gas model: Nucleons = Non-interacting Constrained Fermions

Momentum distribution

\[ \propto \frac{dN}{dk} = \frac{|k|^2}{2\pi^2} \]

for \( k \) up to a (local) Fermi momentum \( k_F(r) \) given by

\[ k_F(r) = \left[ 3\pi^2 \rho_N(r) \right]^{1/3} \]

The Fermi energy \((k_F \approx 1.36 \text{ fm}, P_F \approx 260 \text{ MeV}/c, E_F \approx 35 \text{ MeV}, \text{at nuclear max. density})\) is customarily used in building a self-consistent Nuclear Potential

\[ \text{Depth of the potential well } \equiv \text{Fermi Energy } + \text{Nuclear Binding Energy} \]

Positive kaons as a probe of Fermi motion

\[ K^+ \quad K^0 \]

No low mass \( S=1 \) baryons \( \rightarrow \)
weak \( K^+N \) interaction
only elastic and ch. exch. up to
\( \approx 800 \text{ MeV/c} \)

\( (K^+, K^{+\prime}) \) on Pb vs residual excitation, 705 MeV/c, at \( 24^\circ \) and \( 43^\circ \).

On free nucleon: recoil energy:
43 MeV at \( 24^\circ \), 117 MeV at \( 43^\circ \).
(Generalized) IntraNuclear Cascade

- Primary and secondary particles moving in the nuclear medium
- Target nucleons motion and nuclear well according to the Fermi gas model
- Interaction probability
  \[ \sigma_{\text{free}} + \text{Fermi motion} \times \rho(r) + \text{exceptions (ex. } \pi) \]
- Glauber cascade at higher energies
- Classical trajectories (+) nuclear mean potential (resonant for \( \pi \))
- Curvature from nuclear potential \( \rightarrow \) refraction and reflection
- Interactions are incoherent and uncorrelated
- Interactions in projectile-target nucleon CMS \( \rightarrow \) Lorentz boosts
- Multibody absorption for \( \pi, \mu^-, K^- \)
- Quantum effects (Pauli, formation zone, correlations...)
- Exact conservation of energy, momenta and all additive quantum numbers, including nuclear recoil
hA at high energies: Glauber-Gribov cascade with formation zone

- **Glauber cascade**
  - Quantum mechanical method to compute Elastic, Quasi-elastic and Absorption hA cross sections from Free hadron-nucleon scattering + nuclear ground state
  - Multiple Collision expansion of the scattering amplitude

- **Glauber-Gribov**
  - Field theory formulation of Glauber model
  - Multiple collisions ↔ Feynman diagrams
  - High energies: exchange of one or more Pomerons with one or more target nucleons (a closed string exchange)

- **Formation zone (materialization time)**
**Glauber Cascade**

Quantum mechanical method to compute all relevant hadron-nucleus cross sections from hadron-nucleon scattering:

\[ S_{hN}(\vec{b},s) = e^{i\chi_{hN}(\vec{b},s)} = \eta_{hN}(\vec{b},s)e^{2i\delta_{hN}(\vec{b},s)} \]

and nuclear ground state wave function \( \Psi_i \)

**Total**

\[
\sigma_{hAT}(s) = 2\int d^2\vec{b}\int d^3u|\Psi_i(u)|^2 \left[ 1 - \prod_{j=1}^A \text{Re} S_{hN}(\vec{b} - \vec{r}_{j\perp},s) \right] \]

**Elastic**

\[
\sigma_{hAel}(s) = \int d^2\vec{b}\int d^3u|\Psi_i(u)|^2 \left[ 1 - \prod_{j=1}^A S_{hN}(\vec{b} - \vec{r}_{j\perp},s) \right]^2 \]

**Scattering**

\[
\sigma_{hA\Sigma f}(s) \equiv \sum_f \sigma_{hA\Sigma f}(s) = \int d^2\vec{b}\int d^3u|\Psi_i(u)|^2 \left[ 1 - \prod_{j=1}^A S_{hN}(\vec{b} - \vec{r}_{j\perp},s) \right]^2 \]

**Absorption (particle prod.)**

\[
\sigma_{hAabs}(s) \equiv \sigma_{hAT}(s) - \sigma_{hA\Sigma f}(s) = \int d^2\vec{b}\int d^3u|\Psi_i(u)|^2 \left\{ \prod_{j=1}^A \left( 1 - \left| S_{hN}(\vec{b} - \vec{r}_{j\perp},s) \right|^2 \right) \right\} \]

Absorption probability over a given \( \vec{b} \) and nucleon configuration.
Gribov interpretation of Glauber multiple collisions

Therefore the absorption cross section is just the integral in the impact parameter plane of the probability of getting at least one non-elastic hadron-nucleon collision and the overall average number of collision is given by

\[ \langle \nu \rangle = \frac{Z \sigma_{hp} + N \sigma_{hn}}{\sigma_{hA \text{abs}}} \]

- Glauber-Gribov model = Field theory formulation of Glauber model
- Multiple collision terms ⇒ Feynman graphs
- At high energies: exchange of one or more pomerones with one or more target nucleons

- In the Dual Parton Model language: (neglecting higher order diagrams):
  Interaction with \( n \) target nucleons ⇒ \( 2n \) chains
  - Two chains from projectile valence quarks + valence quarks of one target nucleon ⇒ valence-valence chains
  - \( 2(n-1) \) chains from sea quarks of the projectile + valence quarks of target nucleons ⇒ \( 2(n-1) \) sea-valence chains
Formation zone

Naively: “materialization” time (originally proposed by Stodolski).
Qualitative estimate:

\[ \tau = \frac{M}{E_T} \frac{\Delta t}{\tau} = \frac{\hbar M}{p_T^2 + M^2} \]

In the frame where \( p// = 0 \)

\[ \bar{t} = \Delta t \approx \frac{\hbar}{E_T} = \frac{\hbar}{\sqrt{p_T^2 + M^2}} \]

Particle proper time

Going to the nucleus system

\[ \Delta x_{for} \equiv \beta c \cdot t_{lab} \approx \frac{p_{lab}}{E_T} \bar{t} \approx \frac{p_{lab}}{M} \tau = k_{for} \frac{\hbar p_{lab}}{p_T^2 + M^2} \]

Condition for possible reinteraction inside a nucleus:

\[ \Delta x_{for} \leq R_A \approx r_0 A^{\frac{1}{3}} \]
Effect of Glauber and Formation Zone

Rapidity distribution of charged particles produced in 250 GeV π⁺ collisions on Gold Points: exp. data (Agababyan et al., ZPC50, 361 (1991)).
WARNING

- PEANUT has been extended to cover the whole energy range in late 2006
- A less refined GINC model is available for projectile momenta above about 5 GeV/c, and was the only choice until recently
- However: the extended peanut is NOT yet the default, mainly because of some ambiguity in the definition of quasi-elastic cross sections.
- To activate PEANUT at all energies:

```plaintext
PHYSICS 1000. 1000. 1000. 1000. 1000. 1000. PEATHRESH
```
Nonelastic hA interactions at high energies: examples

Recent results from the HARP experiment at 12.9 GeV/c on Al

Double differential $\pi^+$ production for p C interactions at 158 GeV/c, as measured by NA49 (symbols) and predicted by FLUKA (histograms)
Pions in nuclear medium

Pion-nucleon interactions: non-resonant + p-wave resonant $\Delta$’s.

\[ \Delta \text{ in nuclear medium} \]
\[ \text{decay} \quad \text{reinteraction} \]
\[ \text{elastic scattering or charge exchange} \quad \text{pion absorption} \]
\[ \rightarrow \Delta \text{ width different from the free one} \]

Assuming a Breit-Wigner for the free resonant cross section with width $\Gamma_F$

\[ \sigma_{res}^{\text{Free}} = \frac{8\pi}{p_{cm}^2} \frac{M_\Delta^2 \Gamma_F(p_{cm})^2}{(s - M_\Delta^2)^2 + M_\Delta^2 \Gamma_F(p_{cm})^2} \]

Add “in medium” width (Oset et.al ,NPA 468, 631)

\[ \frac{1}{2} \Gamma_T = \frac{1}{2} \Gamma_F - \text{Im} \Sigma_\Delta, \quad \Sigma_\Delta = \Sigma_{qe} + \Sigma_2 + \Sigma_3 \]

($\Sigma_{qe}, \Sigma_2, \Sigma_3 =$ widths for quasielastic scattering, two and three body absorption)

Add two-body s-wave absorption cross section from optical model

Nuclear potential for $\pi$: Energy dependent, resonant shape (+ Coulomb)
Pion absorption cross section on Gold and Bismuth in the $\Delta$ resonance region (multibody absorption in PEANUT)

Ejected proton spectra at different angles, 160 MeV $\pi^+$ on $^{58}$Ni

Proton spectra extend up to 300 MeV
Preequilibrium emission

For $E > \pi$ production threshold $\rightarrow$ only (G)INC models
At lower energies a variety of preequilibrium models

**Two leading approaches**

- The quantum-mechanical multistep model:
  - Very good theoretical background
  - Complex, difficulties for multiple emissions

- The semiclassical exciton model
  - Statistical assumptions
  - Simple and fast
  - Suitable for MC

**Statistical assumption:**
any partition of the excitation energy $E^*$ among $N$, $N = N_h + N_p$, excitons has the same probability to occur
Step: nucleon-nucleon collision with $N_{n+1} = N_n + 2$ ("never come back approximation")
Chain end = equilibrium = $N_n$ sufficiently high or excitation energy below threshold

$N_0$ depends on the reaction type and cascade history
Thin target example

Angle-integrated $^{90}$Zr(p,xn) at 80.5 MeV

The various lines show the total, INC, preequilibrium and evaporation contributions

Thin target examples

\[ p + ^{90}\text{Zr} \rightarrow p + X \ (80 \text{ MeV}) \]

\[ p + \text{Al} \rightarrow \pi^- + X \ (4 \text{ GeV/c}) \]
High energy light fragments are emitted through the coalescence mechanism: “put together” emitted nucleons that are near in phase space.

Example: double differential $t$ production from $542 \text{ MeV}$ neutrons on Copper

**Warning:** coalescence is OFF by default. Can be important, ex for residual nuclei. To activate it:

If coalescence is on, switch on Heavy ion transport and interactions (see later)
Equilibrium particle emission (evaporation, fission and nuclear break-up)

From statistical considerations and the detailed balance principle, the probabilities for emitting a particle of mass $m_j$, spin $S_j$, $\hbar$ and energy $E$, or of fissioning are given by:

\[ P(J) = \frac{(2S_j + 1)m_j c}{\pi^2 \hbar^3} \int_{v_J}^{U_i-Q_j-\Delta_f} \rho_f(U_f) \frac{\sigma_{inv}(E)}{\rho_i(U_i)} EdE \]

\[ P_{Fiss} = \frac{1}{2 \pi \hbar} \int_{0}^{U_i-B_{Fiss}} \frac{\rho_{Fiss}(U_i-B_{Fiss}-E)}{\rho_i(U_i)} dE \]

- $\rho$'s: nuclear level densities
- $U$'s: excitation energies
- $V$'s: possible Coulomb barrier for emitting a particle type $j$
- $B_{Fiss}$: fission barrier
- $Q$'s: reaction $Q$ for emitting a particle type $j$
- $\sigma_{inv}$: cross section for the inverse process
- $\Delta$'s: pairing energies

**Neutron emission is strongly favoured because of the lack of any barrier**

**Heavy nuclei generally reach higher excitations because of more intense cascading**
Equilibrium particle emission

- **Evaporation**: Weisskopf-Ewing approach
  - ~600 possible emitted particles/states (A<25) with an extended evaporation/fragmentation formalism
  - Full level density formula with level density parameter A,Z and excitation dependent
  - Inverse cross section with proper sub-barrier
  - Analytic solution for the emission widths (neglecting the level density dependence on U, taken into account by rejection
  - Emission energies from the width expression with no. approx.

- **Fission**: past, improved version of the Atchison algorithm, now
  - $\Gamma_{\text{fis}}$ based of first principles, full competition with evaporation
  - Improved mass and charge widths
  - Myers and Swiatecki fission barriers, with exc. en. Dependent level density enhancement at saddle point

- **Fermi Break-up for A<18 nuclei**
  - ~50000 combinations included with up to 6 ejectiles
  - $\gamma$ de-excitation: statistical + rotational + tabulated levels
Residual Nuclei

- The production of residuals is the result of the last step of the nuclear reaction, thus it is influenced by all the previous stages
- Residual mass distributions are very well reproduced
- Residuals near to the compound mass are usually well reproduced
- However, the production of specific isotopes may be influenced by additional problems which have little or no impact on the emitted particle spectra (Sensitive to details of evaporation, Nuclear structure effects, Lack of spin-parity dependent calculations in most MC models)
Example of fission/evaporation

- Quasi-elastic products
- Spallation products
- Deep spallation products
- Fission products
- Fragmentation products
- Evaporation products

Residual nuclei

Experimental and computed residual nuclei mass distribution for Ag(p,x)X at 300 GeV

The fragmentation model has much improved the FLUKA predictions

Also for A-A interactions

Warning: fragmentation is OFF by default, because it is a cpu-eater. It is NECESSARY to activate it for activation studies:

If fragmentation is on, switch on Heavy ion transport and interactions (see later)
