Geometry directives

Special commands enclosing body definition:

$Start_xxx

  ....

$End_xxx

> where "xxx" stands for "expansion", "translat" or "transform"

They provide respectively a coordinate expansion/reduction, a coordinate translation or a coordinate roto-translation of the bodies embedded between the starting and the ending directive lines.

Directives in geometry: expansion/reduction

➢ $Start_expansion ... $End_expansion

it provides a coordinate expansion (reduction) factor f for all bodies embedded within the directive

$Start_expansion 10.0
SPH Sphere 5.0 7.0 8.0 50.0
$End_expansion
transforms a sphere of radius 50 centered in (+5,+7,+8)
into a sphere of radius 500 centered in (+50,+70,+80)

Putting the body in its quadric form

$$A_{xx} x^2 + A_{yy} y^2 + A_{zz} z^2 + A_{xy} xy + A_{xz} xz + A_{yz} yz + A_x x + A_y y + A_z z + A_0 = 0$$

or $\begin{bmatrix} x & y & z & 1 \end{bmatrix} \begin{bmatrix} A_{xx} & A_{xy}/2 & A_{xz}/2 & A_x/2 \\ A_{xy}/2 & A_{yy} & A_{yz}/2 & A_y/2 \\ A_{xz}/2 & A_{yz}/2 & A_{zz} & A_z/2 \\ A_x/2 & A_y/2 & A_z/2 & A_0 \end{bmatrix} \begin{bmatrix} x \\ y \\ z \\ 1 \end{bmatrix} = 0$ i.e. $\mathbf{r^T} M_{QUA} \mathbf{r} = 0$

the expansion/reduction matrix is $T = \begin{bmatrix} f & 0 & 0 & 0 \\ 0 & f & 0 & 0 \\ 0 & 0 & f & 0 \\ 0 & 0 & 0 & 1 \end{bmatrix}$

and the transformed body equation is $\mathbf{r}^T (T^{-1})^T M_{QUA} T^{-1} \mathbf{r} = 0$

4

Directives in geometry: translation

➢ $Start_translat ... $End_translat

it provides a coordinate translation S_x, S_y, S_z for all bodies embedded within the directive

$Start_translat -5.0 -7.0 -8.0
SPH Sphere 5.0 7.0 8.0 50.0
$End_translat
transforms a sphere of radius 50 centered in (+5,+7,+8)
into a sphere of radius 50 centered in (0,0,0)

the translation matrix is $T = \begin{bmatrix} 1 & 0 & 0 & S_x \\ 0 & 1 & 0 & S_y \\ 0 & 0 & 1 & S_z \\ 0 & 0 & 0 & 1 \end{bmatrix}$

Directives in geometry: roto-translation

➢ $Start_transform ... $End_transform

it applies a pre-defined (via ROT-DEFI) roto-translation to all bodies embedded within the directive

```
ROT-DEFI , 201.0, 0., +116.5650511770780, 0., 0., 0., cylrot
$Start_transform cylrot
QUA Cylinder 0.5 1.0 0.5 0.0 1.0 0.0 0.0 0.0 0.0 -4.0
$End_transform
```
transforms an infinite circular cylinder of radius 2 with axis {x=-z,y=0}
into an infinite circular cylinder of radius 2 with axis {x=z/3,y=0} (**clockwise rotation**)

the roto-translation matrix is

$$T = \begin{bmatrix} & & & S_x \\ & R & & S_y \\ & & & S_z \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

$$T^{-1} = \begin{bmatrix} & & & -(R^{-1}S)_x \\ & R^{-1} & & -(R^{-1}S)_y \\ & & & -(R^{-1}S)_z \\ 0 & 0 & 0 & 1 \end{bmatrix}$$

- it allows to rotate a RPP avoiding the use of the deprecated BOX !

- note that also the **inverse** transformation can be used T^{-1}

$Start_transform -cylrot

ROT-DEFIni

The ROT-DEFIni card defines roto-translations that can be applied, in addition to bodies, to i. USRBIN & EVENTBIN and ii. LATTICE. It transforms the position of the tracked particle i. before scoring with respect to the defined binning or ii. into the prototype with the order:

- First applies the translation
- followed by the rotation on the azimuthal angle
- and finally by the rotation on the polar angle.

$$X_{new} = M_{polar} \times M_{az} \times (X + T)$$

WHAT(1): assigns a transformation index and the corresponding rotation axis **I + J * 100**   or   **I * 1000 + J**

   I = index of rotation   (WARNING: NOTE THE SWAP OF VARIABLES)
   J = rotation with respect to axis (1=X, 2=Y, 3=Z)

WHAT(2): Polar angle of the rotation ($0 \leq \vartheta \leq 180^o$ degrees)

WHAT(3): Azimuthal angle of the rotation ($-180 \leq \varphi \leq 180^o$ degrees)

WHAT(4), WHAT(5), WHAT(6) = X, Y, Z offset for the translation

SDUM: Optional (but recommended) name for the transformation

ROT-DEFI	Id: 1	Axis: Z ▼	Name: 1tra
	Polar: 0.0	Azm:	
	Δx:	Δy:	Δz: -10.0

Directives in geometry: warnings

➤ **$Start_expansion** and **$Start_translat** are applied when reading the geometry → no CPU penalty (the concerned bodies are transformed once for ever at inizialization)

$Start_transform is applied runtime → some CPU penalty

➤ One can **nest** the different directives *(at most one per type!)* but, no matter the input order, the adopted sequence is always the following:

$Start_transform StupiRot

$Start_translat -5.0 -7.0 -8.0

$Start_expansion 10.0

`QUA WhatIsIt +1.0 +1.0 +1.0 0.0 0.0 0.0 -10.0 -14.0 -16.0 -2362.0`

$End_expansion

$End_translat

$End_transform

➤ Directives are not case sensitive (whereas roto-translation names are)

Identifying rotation angles

Let's define the orientation of a body in the space
by a system of 3 orthogonal vectors **i′**, **j′**, **k′** , whose coordinates
are expressed with respect to the fixed reference frame X,Y,Z

Then $\quad [\ \mathbf{i'}\ \ \mathbf{j'}\ \ \mathbf{k'}\ ] = \begin{bmatrix} c_1 c_3 - c_2 s_1 s_3 & -c_1 s_3 - c_3 c_2 s_1 & s_2 s_1 \\ c_2 c_1 s_3 + c_3 s_1 & c_1 c_2 c_3 - s_1 s_3 & -c_1 s_2 \\ s_3 s_2 & c_3 s_2 & c_2 \end{bmatrix} \begin{bmatrix} X \\ Y \\ Z \end{bmatrix}$ (in the ZXZ convention)

where $\quad c_1 = \cos(\psi) \quad c_2 = \cos(\theta) \quad c_3 = \cos(\Phi) \quad s_1 = \sin(\psi) \quad s_2 = \sin(\theta) \quad s_3 = \sin(\Phi)$
here $\quad \Phi = 45^\circ \qquad \theta = 30^\circ \qquad \psi = -60^\circ$

The obtained Euler angles can be input as azimuthal angle of
three consecutive rotations (ROT-DEFI)

Lattice

FLUKA geometry has *replication* (lattice) capabilities

Only one *level is implemented* (no nested lattices are allowed)

- The user defines lattice positions in the geometry and provides transformation rules from the lattice to the prototype region:
    1. in the input with the ROT-DEFI card
    2. in a subroutine (lattic.f)

The lattice identification is available for scoring

Transformations include:
Translation, Rotation and Mirroring (the last only through routine).

Lattice

- The regions which constitute the elementary cell *(prototype)* to be replicated, have to be defined in detail

- The Lattices *(replicas/containers)* have to be defined as "empty" regions in their correct location.
  WARNING: The lattice region should map exactly the outer surface definition of the elementary cell.

- The lattice regions are declared as such with a LATTICE card at the end of the geometry input

- In the LATTICE card, the user also assigns lattice names/numbers to the lattices. These names/numbers will identify the replicas in all FLUKA routines and scoring

- Several basic cells and associated lattices can be defined within the same geometry, one LATTICE card will be needed for each set

- Non-replicas carry the lattice number **0**

- Lattices and plain regions can coexist in the same problem

LATTICE card

After the Regions definition and before the GEOEND card the user can insert the LATTICE cards

- **WHAT(1), WHAT(2), WHAT(3)**
  Container region range (from, to, step)

- **WHAT(4), WHAT(5), WHAT(6)**
  Name/number(s) of the lattice(s)

- **SDUM**
  blank   to use the transformation from the lattic routine
  ROT#nn   to use a ROT-DEFI rotation/translation from input
  name   the same as above but identifying the roto-translation by the name
  assigned in the ROT-DEFI SDUM (any alphanumeric string you like)

Example

```
LATTICE              Reg: TARGR1 ▼      to Reg:  ▼          Step:
    Id: 1tra ▼       Lat: 1.0           to Lat: 1.0         Step: 1.0
```

```
*...+....1....+....2....+....3....+....4....+....5....+....6....+....7....+...
LATTICE          6.00000   19.00000              101.0000     114.00
```
Region # 6 to 19 are the "placeholders" for the first set replicas. We assign to them lattice numbers from 101 to 114
```
LATTICE          TARGR1                        TargRep                    1tra
```
TARGR1 is the container region using transformation *1tra*

Example

Prototype regions

Empty lattice container

Example

Replica

Transformation

Prototype regions

For every particle entering the replica

Its coordinates are transformed to the prototype, where FLUKA performs the tracking

Example

Prototype cell

Empty lattice cell

Final replica

Transformation by input

- Rotations/Translations can be defined with the ROT-DEFIni card

- Can be assigned to a lattice by name or with ROT#nnn SDUM in the LATTICE card

- ROT-DEFIni cards can be consecutive (using the same index or name) to define complex transformations

WARNING:

Since matrix multiplication is not commutative the order of the Rotation/Translation operations in 3D is important.

Numerical Precision

- Due to the nature of the floating point operations in CPU, even if the transformation looks correct the end result could be problematic

This small misalignment between lattice/transformation/prototype could lead to geometry errors

- Use as many digits as possible to describe correctly the prototype and lattice cells as well as the transformation.
  It is mandatory that the transformation applied to the container makes the latter EXACTLY corresponding to the prototype

- One can use a FREE and FIXED card before and after the ROT-DEFI to input more than 9 digits

- GEOBEGIN WHAT(2) allows to relax the accuracy in boundary identification (USE WITH CAUTION)

Lattice: Important remarks

- Materials and other properties have to be assigned only to the regions constituting the prototype.

- In all (user) routines the region number refers to the corresponding one in the prototype.

- The SCORE summary in the .out file and the scoring by regions add together the contributions of the prototype region as well as of all its replicas!

- The lattice identity can be recovered runtime by the *lattice number*, as set in the LATTICE card or available through the GEON2L routine if is defined by name

- In particular, the LUSRBL user routine allows to manage the scoring on lattices in the special USRBIN/EVENTBIN structure.

The USRBIN/EVENTBIN special binning

EVENTBIN or USRBIN with WHAT(1)=**8** :

Special user-defined 3D binning. Two variables are discontinuous (e.g. region number), the third one is continuous, but not necessarily a space coordinate.

Variable	Type	Default	Override Routine
1st	integer	region number	MUSRBR
2nd	integer	lattice cell number	LUSRBL
3rd	float	zero	FUSRBV

Tips & Tricks

- Always remember that the transformation must bring the container onto the prototype and not viceversa!

- You can always divide a transformation into many ROT-DEFI cards for easier manipulation.

- Rotations are always around the origin of the geometry, and not the center of the object.
  - To rotate an object, first translate the object to the origin of the axes
  - Perform the rotation
  - Move it by a final translation to the requested position.
    Of course with the inverse order since everything should apply to the replica

- In order to define the replica body, you can clone the body enclosing the prototype (assigning it a new name!) and apply to it the $Start_transform directive with the inverse of the respective ROT-DEFI transformation.

Tips & Tricks
GEOBEGIN

…

RPP CollProt -540.0 -460.0 -20.0 20.0 100.0 300.0
$start_transform **–rotColl** *
RPP CollRepl -540.0 -460.0 -20.0 20.0 100.0 300.0
$end_transform

…

GEOEND

ROT-DEFI, 1.0, 0.0, 0.0, 0.0, 0.0, -350.0, rotColl   [A]
ROT-DEFI, 201.0, 0.0, -15.0, 0.0, 0.0, 0.0, rotColl   [B]
ROT-DEFI, 1.0, 0.0, 0.0, -500.0, 0.0, 200.0, rotColl   [C]

* Remember: if R=CBA, then $R^{-1}=A^{-1}B^{-1}C^{-1}$

(Tips & Tricks)

- The Geometry transformation editor in flair can read and write ROT-DEFI cards with the transformation requested

- An easy way of creating a replica and the associated transformation is the following:

  1. Select the body defining the outer cell of the prototype
  2. Clone it with (Ctrl-D) and change the name of the clones. Click on "No" when you are prompted to change all references to the original name.
  3. Open the Geometry transformation dialog (Ctrl-T)
  4. Enter the transformation of the object in the listbox
  5. Click on "Transform" to perform the transformation on the clone bodies
  6. Click on "Invert" button to invert the order of the transformation
  7. Enter a name on the "ROT-DEFIni" field and click "Add to Input" to create the ROT-DEFIni cards
  8. Now you have to create manually the needed regions and the LATTICE cards

The FLUKA voxel geometry

It is possible to describe a geometry in terms of "voxels", i.e., tiny parallelepipeds (all of equal size) forming a 3-dimensional grid
An example
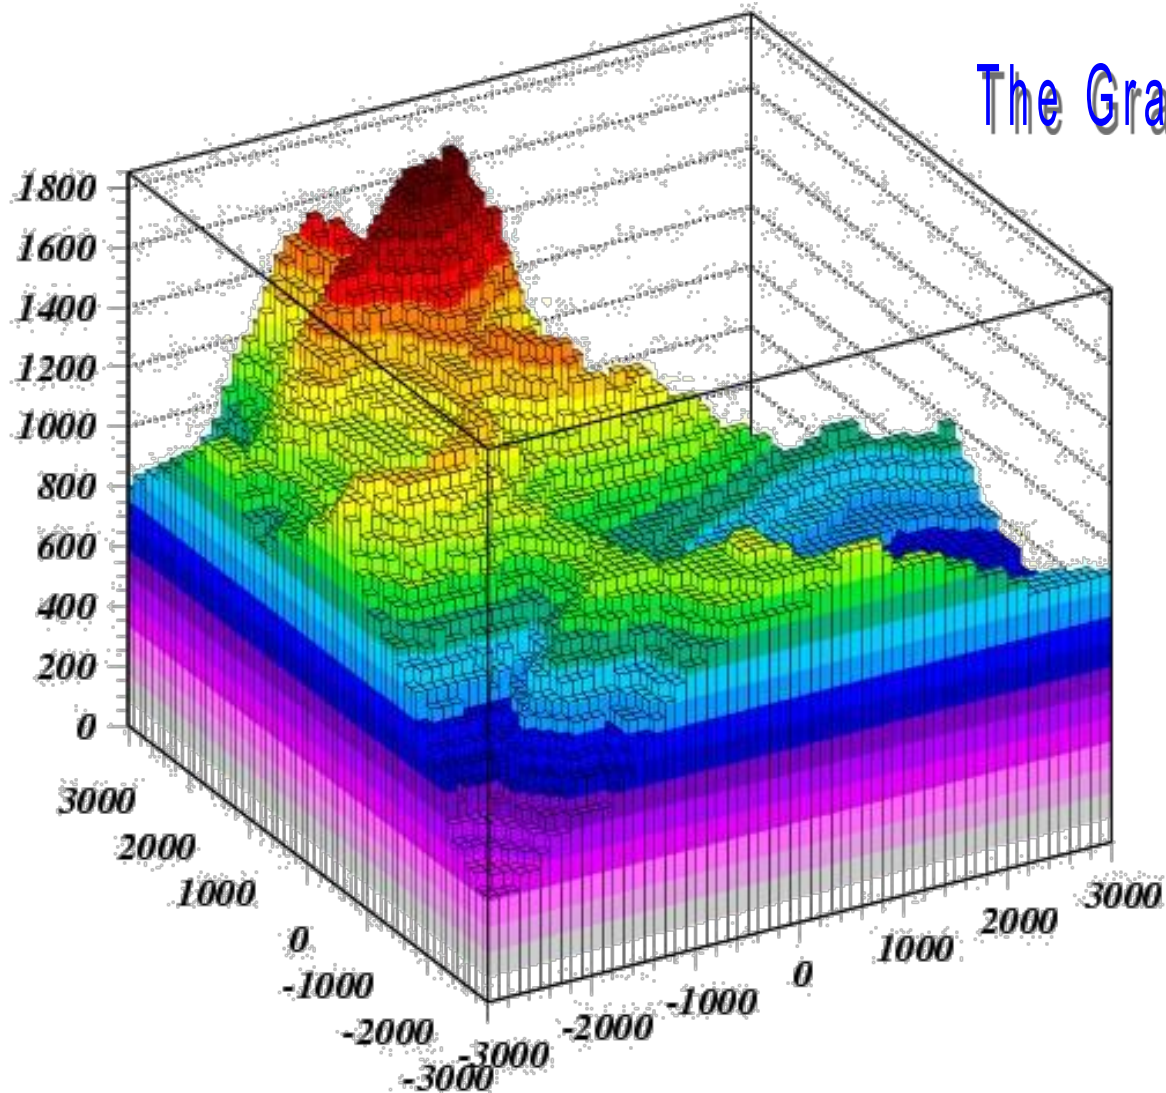

The Gran Sasso in FLUKA

Another example, for medical applications

Voxel geometries are especially useful to import CT scan of a human body, e.g., for dosimetric calculations of the planned treatment in radiotherapy

[K. Parodi et al., 2007]

Concepts

- The CT scan contains integer values "Hounsfield Unit" reflecting the X-ray attenuation coefficient μ_x

  $$HU_x = 1000\,(\mu_x - \mu_{H20})\,/\,\mu_{H20}\,,\ \text{typically } -1000 \leq HU \leq 3500$$

- We will use loosely the word "organ" to indicate a group of voxels (or even more than one group) made of the same "tissue" material (same HU value or in a given HU interval)

- The code handles each organ as a CG region, possibly in addition to other conventional "non-voxel" regions defined by the user

- The voxel structure can be complemented by parts written in the standard Combinatorial geometry

- The code assumes that the voxel structure is contained in a parallelepiped. This RPP is automatically generated from the voxel information.

Procedure

- To describe a voxel geometry, the user must convert his CT scan or equivalent data to a format understood by FLUKA

- This stage should :

  - Assign an organ index to each voxel. In many practical cases, the user will have a continuum of CT values (HU), and may have to group these values in intervals

  - Each organ is identified by a unique integer ≤32767. The organ numbering does not need to be contiguous (i.e. "holes" in the numbering sequence are allowed.)

  - One of the organs must have number **0** and plays the role of the medium surrounding the voxels (usually vacuum or air).

  - The user assigns to each NONZERO organ a voxel-region number. The voxel-region numbering has to be contiguous and starts from 1.

Procedure

- The information is input to FLUKA through a special **unformatted** file *vxl containing:
  - The number of voxels along each coordinate axis
  - The number of voxel-regions, and the maximum organ number
  - The voxel dimension along each coordinate axis
  - A 3D matrix specifying the organ to which each voxel corresponds in Fortran list-oriented format, with the x coordinate running faster than y, and y running faster than z.

val(1)	corresponds to 1,1,1 == organ # of first voxel
…	…
val(N_x)	corresponds to N_x,1,1
val(N_x+1)	corresponds to **1,2**,1
…	…
val(2*Nx)	corresponds to N_x,2,1
…	
val(N_y*N_x)	corresponds to N_x,N_y,1
…	…
val(N_z*N_y*N_x)	corresponds to N_x,N_y,N_z == organ # of last voxel

  - A list of the voxel-region number corresponding to each organ

Input file: geometry description

Prepare the usual FLUKA input file.

The geometry is written like a normal Combinatorial Geometry input, but in addition a VOXELS card must be inserted right after the GEOBEGIN card and before the Geometry title card

- WHAT(1), WHAT(2), WHAT(3) = x, y, z coordinates chosen as the origin of the "voxel volume", i.e. the corner of a RPP extending from WHAT(1) to WHAT(1) + NX*DX, … and containing all the voxels
- WHAT(4) possible ROT-DEFI **transformation applying to the RPP**
- (WHAT(5), WHAT(6): not used)
- SDUM = name of the voxel file
  (extension will be assumed to be .vxl)

```
VOXELS    -20.0    -30.0    -40.0  transf            ct
```

Input file: geometry description

One will have

- The usual list of NB bodies, not including the RPP corresponding to the "voxel volume" (see VOXELS card above). This RPP will be generated and added automatically by the code as the (NB+1) [th] body, with one corner in the point indicated in the VOXELS card, and dimensions NX*DX, NY*DY and NZ*DZ as read from the voxel file.

- The usual list of NR regions, with the space occupied by the body named VOXEL or numbered NB+1 (the "voxel volume") subtracted. In other words, the NR listed regions must cover the whole available space, except the space corresponding to the "voxel volume". This is easily obtained by subtracting the body VOXEL (or NB+1) in the relevant region definitions, even though this body is not explicitly input at the end of the body list.

```
* vacuum inside
VACI      5 +SHI +SHTB -SHBT -VOXEL
```

Voxel Regions

The code will automatically generate NO+2 additional regions, where NO = number of non-zero organs:

Name	Number	Description
VOXEL	NR+1	sort of a "cage" for all voxels. Nothing should ever be deposited in it. The user shall assign VACUUM to it.
VOXEL001	NR+2	containing all voxels belonging to organ number 0. There must be at least 2 of such voxels, but in general they should be many more. Typical material assignment to this region is air
VOXEL002	NR+3	corresponding to organ 1
VOXEL003	NR+4	corresponding to organ 2
VOXEL###	NR+2+NO	corresponding to organ NO

Voxel Material Assignment

The assignment of materials shall be made by the card ASSIGNMAt (and in a similar way for other region-dependent options) referring to the first NR regions in the usual way, and to the additional voxel regions using the correspondence to organs.

```
            ASSIGNMA   BLCKHOLE    BLKH
            ASSIGNMA    VACUUM     VACO
            ASSIGNMA   ALUMINUM      AL
            ASSIGNMA    VACUUM     VACI
cage        ASSIGNMA    VACUUM    VOXEL
0 Organ     ASSIGNMA    VACUUM  VOXEL001
            ASSIGNMA   TITANIUM  VOXEL002
6 "Non-     ASSIGNMA      AIR VOXEL003
zero"       ASSIGNMA   COPPER VOXEL004
organs      ASSIGNMA   CALCIUM VOXEL005
            ASSIGNMA   CARBON VOXEL006
            ASSIGNMA      AIR VOXEL007
```

Summary of the relevant input cards

$Start_expansion $End_expansion

$Start_translat $End_translat   (inside the geometry input)

$Start_transform $End_transform

 to manipulate bodies

ROT-DEFI

 to define roto-translations

LATTICE (inside the geometry input)

 to declare a region as a replica placeholder and associate it to a given transformation

VOXEL (inside the geometry input)

 to introduce a voxel geometry
